Abstract [Authors' English summary modified]: Eleven identical viral strains were isolated in embryonate hen eggs that had been inoculated intra-amniotically with Hodgkin products. Five of these strains were adapted to the white mouse after intranasal inoculation. A constantly lethal disease with an incubation period of four to five days was caused by the adapted mouse virus, whether administered intranasally, intraperitoneally, intracerebrally, intramuscularly, subcutaneously or intravenously. The virus was

"Specific Prophylaxis in Measles. I. The Preparation of a Vaccine with Modified Live Virus."

Bucharest, Studii si Cercetari de Inframicrobiologie, Vol 17, No 5, 66, pp 371-376.

Abstract: The preparation of an anti-measles vaccine with modified M60-5^H virus on human embryo kidney cells is reported. The vaccine proved harmless for guinea pigs and white mice, and did not produce anaphylactic phenomena in guinea pigs. Anti-measles hemagglutination-inhibiting antibodies in titers of 1/640 to 1/960 were developed in the immunized animals both against the homologous strain and against the MN and Edmonston strains. Includes 2 tables, 6 figures and 19 references, of which 4 Rumanian, 2 Russian, 2 Chinese, 2 German and 9 Western. -- Manuscript submitted 4 June 1966.

of a Vaccine Prepared with Modified Live Virus."

Bucharest, Studii si Cercetari de Infracrobiologie, Vol 17,
No 5, 66, pp 377-387.

Abstract: An anti-measles vaccine prepared with modified live
M60-5Huang virus was tested on 220 children. Only minor clinical
reactions resulted, with a complete absence of rashes or con-
vulsions. One month after vaccination serum conversion was 79.41
percent, and the titer of anti-measles hemagglutination-inhibiting
antibodies varied between 1/80 and 1/320. After 4 months the
corresponding values were 75 percent and 1/40 to 1/80. Thus the
vaccination seems to confer a specific immunity, which so far has
protected the vaccinated children against measles.

"Data Concerning the Current Concepts on the Virus Origin of Cancer"

Bucharest, Natura, Seria Biologie, Vol. 18, No. 3, May-June, 66, pp. 21-4.

Abstract: From the experimental data and theories concerning the origin of cancer, only those supporting the virus origin of this disease have been selected. Borrel in 1903 formulated the first hypothesis of a viral etiology of cancer. Subsequently this theory was experimentally verified in a large number of cases. In 1952 S. Nicolau emphasized the "quasi-general" property of the virus to stimulate the tissues until, under certain conditions, neoplasms are formed. A number of famous scientists from all over the world support the point of view that viruses appear in the development of tumors. The most recent concept of carcinogenesis was discussed at the Eighth International Cancer Congress in 1962. Without proliferation and modification of the nucleus a malignant growth is not possible.

TEXT: The production and properties of high-strength, chemically modified and polynose fibers are discussed. Methods of modifying viscose fibers, and the modifiers used for this, are indicated. The properties of the viscose fiber are improved by the following means: adding modifiers to the viscose during the process of its preparation; introducing the technology of producing polynose fiber with a high modulus of elasticity; modification of the cellulose; using copolymerization etc. The new forms of viscose fiber, among them polynose fiber, which have a number of advantages over ordinary viscose fiber are being put into production and their rate of production will continually increase. AUTHOR: Josef Čajka (Engineer)

TITLE: On Calculating the Elements of an Equivalent Circuit with an Ideal Power Gyrator

PERIODICAL: Slaboproudý Obzor, 1960, Vol 21, Nr 1, pp 56-57

ABSTRACT: It is sometimes necessary to convert an Z -mode (Fig 1a) from reciprocal quadripole into an equivalent reciprocal π (Fig 1b) or T -type (Fig 1c) quadripole by means of an ideal power gyrator. The progression matrix of such a reciprocal quadripole, a , is expressed by Eq (2) where the parameters A, B, C, D, M and W can be evaluated from the sub-determinant of the admittance matrix of the original quadripole. From Eq (2) it is possible to calculate the impedances or admittances of the equivalent reciprocal quadripoles. The required conversion formulae are given by Eqs (4) and (5). The procedure is illustrated by a numerical example of a simple amplifier (Fig 2). There are 2 figures and 3 Czech references.

TITLE: A contribution to the design of amplifiers with
matched output impedance

PERIODICAL: Slaboproudý obzor, v. 22, no. 12, 1961, 716-719

TEXT: The author demonstrates a method for calculating the ratio of audio frequency transformers in a final stage circuit of group amplifiers with multiple-loop feedback when matching is required on the input and output side as well as small nonlinear distortion and an optimum value of the load for the active dependent element, either a pentode or transistor. The author bases his calculation on a transmission element with n independent linear loops (circuits), where the feed generator of the internal impedance (Z_g) is connected to the input loop and the load impedance (Z_z) is connected to the output loop. For the entire transmission element, an impedance matrix (Z) can easily be established. Based on this

Card 1/2

A contribution to the design ...

Z/039/61/022/012/001/009

matrix, the following four equations are derived: (a) the input impedance of the amplifier stage, (b) its output impedance, (c) the voltage gain, (d) the current gain. The author points out that even in the case of a relatively simple connection, the calculations are rather complicated and the relations are difficult to arrive at, if one wishes to obtain the requirements described above. A solution, however, is possible with the help of sequential approximations which must be established individually for each particular design. An example of such an iterative calculation process is given for one possible end stage connection. There are 6 figures and 4 Soviet-bloc references.

TITLE: A matrix method of solving circuits with parametric dipoles in the steady state

SOURCE: Elektrotechnicky casopis, no. 6, 1964, 321-331

TOPIC TAGS: circuit, parametric amplifier, frequency converter, circuit research

ABSTRACT: A description is given of a simple, universal method of solving a circuit system with parametric dipoles (f. i., parametric amplifiers, frequency converters etc.) in the steady state. The method uses data from the matrix interpretation of the knot voltage method for the solution of a linear circuit system with parameters not varying with time. The parametric dipoles and time invariable the dipoles are characterized by component matrices of admittance. The method is advantageous mainly in the solution of circuits with selective elements, which reduce the number of the frequency spectrum components. The initial matrix equation between the components of the knot currents and the knot voltages can be constructed according to simple rules directly from the principal scheme of the network without auxiliary or equivalent schemes.
